Abstract

A fabrication route based on aqueous colloidal processing plus transient liquid-phase assisted spark-plasma-sintering (SPS) with Ti-Al additives is described for the environmentally friendly obtention of superhard B₄C composites reinforced with reduced graphene oxide (rGO) having orthotropic and isotropic microstructures. It is shown that the former, which have coarse rGO platelets preferentially aligned perpendicular to the SPS pressing direction, can be prepared from mixtures of B₄C and Ti-Al particles with a source of thick, large rGO nanoplatelets by imposing smooth co-dispersion conditions to avoid platelet re-exfoliation and fragmentation. The latter, which have fine rGO platelets randomly oriented, can be fabricated from mixtures of B₄C and Ti-Al particles with a source of thin, small rGO nanoplatelets by applying intensive sonication to promote platelet re-exfoliation and fragmentation during co-dispersion. Finally, it is shown that these orthotropic and isotropic B₄C/rGO composites are equally superhard, and that, as expected, their microstructures interact differently with the cracks. Finally, this processing route is simple, and easily adaptable/extensible to make other ceramic/rGO composites with orthotropic and isotropic microstructures.

1. Introduction

B₄C-based ceramics are receiving growing attention lately as one of the most promising types of structural material for use in contact-mechanical and tribological applications [1-10]. What makes B₄C particularly appealing over other advanced structural ceramics is its super-hardness and ultra-lightweight, which are very important attributes in many structural applications (essential for example in the field of personnel and vehicle armour). Despite their great promise as advanced structural ceramics, widespread implementation of B₄C-based ceramics is still very limited because they are hard to sinter [4,11] and brittle [1,12]. The former is mitigated using sintering aids [4,13,14] and/or non-conventional sintering (in particular, spark-plasma sintering (SPS)) [15-20]. The latter is palliated by forcing cracks to in some way interact intensely with the microstructure (microstructural toughening) [21,22].

Following the classical approach of toughening brittle ceramics with fibres, whiskers, and platelets [21,22], it is today more popular to use carbon nanostructures as reinforcements. These include zero-dimensional (0-D) carbon nanoparticles (CNPs), one-dimensional (1-D) carbon nanotubes (CNTs), and two-dimensional (2-D) graphene nanoplatelets or their 2-D derivatives (i.e., nanoplatelets of graphene oxide (GO), partially-reduced graphene oxide (prGO), or reduced graphene oxide (rGO)). CNPs have little toughening effect, but act efficiently as internal solid lubricants in wear applications [23]. CNTs, however, have been widely used as toughening reinforcements [24,25], and it has been revealed that they exhibit a unique crack-bridging toughening mechanism [26]. Reinforcement with 2-D carbon nanoplatelets has been far less studied despite their being in principle potentially more effective in bridging cracks [27] and more easily dispersible in ceramic matrices [24]. Very recently, novel *in situ* observations of crack propagation in Al₂O₃ ceramics reinforced with rGO nanoplatelets have identified why

1
2
3
4 these composites are tougher, and have shown the marked importance of the size and orientation
5
6 of those nanoplatelets [28]. The ceramic/rGO composites are sometimes unintentionally
7
8 “orthotropic” because the uniaxial pressure applied during SPS results naturally in
9
10 microstructures with rGO nanoplatelets aligned perpendicularly to the compaction direction.
11
12 Others, however, are fortuitously isotropic. Importantly, it has been shown that the orthotropic
13
14 ceramic composites reinforced with coarse rGO nanoplatelets are markedly tough for cracks
15
16 propagating with their front normal to the rGO nanoplatelets [28], while the isotropic ceramic
17
18 composites reinforced with randomly-oriented fine rGO nanoplatelets are moderately tough in all
19
20 directions [28].
21
22
23
24
25

26 B₄C is no exception, and, although few, there have already been studies on B₄C/rGO
27
28 composites reporting both orthotropic and isotropic microstructures. They have, however, been
29
30 fabricated somewhat uncontrollably by very varied processing routes (heterogeneous co-
31
32 precipitation plus ex-situ reduction and SPS [29], self-assembly polymerization plus SPS [30],
33
34 high-energy rotary-vibratory milling plus hot-pressing [31-34], ultrasonic dispersion plus hot-
35
36 pressing [35], attrition milling plus hot-pressing [36], diluted wet-dispersion plus SPS [37], etc.),
37
38 some of which are certainly complex. It thus appeared especially timely to explore how to turn
39
40 the orthotropic and isotropic microstructural designs into reality for B₄C/rGO by one given
41
42 simple processing route, in a controlled manner. This was indeed the objective of the present
43
44 study, which is specifically aimed at developing an environmentally friendly fabrication route
45
46 combining aqueous colloidal processing with transient liquid-phase assisted SPS of B₄C with Ti-
47
48 Al additives that enables the controlled obtention of one or the other microstructure depending
49
50 on the source of rGO nanoplatelets and on the conditions of colloidal co-dispersion used. The
51
52 motivation for processing controllably these types of B₄C/rGO composites is because toughened,

3
4 superhard materials based on B₄C have great potential for myriad of engineering applications,
5
6 and the ceramics industry demands fabrication processes for the mass production of parts that are
7
8 well established.
9

10 11 12 13 14 **2. Experimental procedure**

15 16 ***2.1. Aqueous colloidal processing of the powder mixtures***

17
18 The starting materials were commercially available powders of B₄C (Grade HD 20, H.C.
19 Starck, Germany), Ti-Al (22895, Alfa Aesar, Germany), GO (1.8, Abalonyx AS, Norway), and
20 prGO (2.1, Abalonyx AS, Norway) with the features indicated in Table 1, as well as a
21 commercially available cationic polyelectrolyte (polyethylenimine (PEI); MW ~25,000; Sigma-
22 Aldrich, USA). Note that (i) Ti-Al is the transient liquid-phase sintering additive for B₄C [38,39],
23 and that (ii) GO and prGO are the source of rGO for the orthotropic and isotropic B₄C/rGO
24 composites, respectively. From these four powders, mixtures of B₄C+Ti-Al+GO and B₄C+Ti-
25 Al+prGO, designed to yield B₄C composites with 4.9 vol.% Ti-Al and 2 vol.% rGO, were
26 prepared by aqueous colloidal processing, as described below. These concentrations of Ti-Al and
27 rGO were chosen because earlier studies have shown that they optimize the SPS densification
28 [38] and mechanical properties [29], respectively, of the B₄C composites.
29
30

31
32 Firstly, the appropriate proportion (wt.%) of PEI deflocculant for dispersing the
33 GO/prGO powder in water at neutral pH was identified by studies of colloidal stability through
34 zeta potential measurements (Zetasizer Nano-ZS, Malvern, UK). These measurements were done
35 on dilute aqueous suspensions (0.1 g/l; KCl 10⁻² M as inert electrolyte) of the GO/prGO powders
36 without and with different PEI additions, after their sonication for 1 min and equilibration for

4 <10 min. The colloidal stability in water of the B₄C and Ti-Al powders is already known [40],
5
6 and therefore the study was not repeated.
7

8
9 Secondly, the appropriate homogenization conditions for preparing at neutral pH aqueous
10 suspensions of both B₄C+Ti-Al+GO and B₄C+Ti-Al+prGO as concentrated as possible were
11 identified by rheological studies (MARS, Haake, Thermo, Germany). These studies were
12 performed on suspensions with different total solids loadings, prepared under continuous
13 mechanical agitation (at 310 rpm) according to the following sequence: (1) addition to the de-
14 ionized water of the PEI content required to disperse the GO/prGO powder, and agitation for 1
15 min; (2) gradual incorporation of the GO/prGO powder, and agitation for 5 min; (3) addition of
16 the PEI content required to disperse the Ti-Al and B₄C powders, and agitation for 1 min; (4)
17 introduction of the Ti-Al powder, and agitation for 15 min; and (4) gradual addition of the B₄C
18 powder, adjustment of the pH to neutral pH, agitation for 30 min, and pulsed sonication (UP-
19 400S, Hielscher Ultrasonics GmbH, Germany) at 240 W for the desired time. The flow curves
20 were measured operating the rheometer, configured in the double cone-plate geometry, in
21 controlled shear rate mode (from 0 to 1000 s⁻¹ in 300 s, then a plateau at 1000 s⁻¹ for 60 s, and
22 lastly from 1000 to 0 s⁻¹ also in 300 s).

2.2. Spark-plasma sintering of the B₄C/rGO composites

The powder mixtures of B₄C+Ti-Al+GO and B₄C+Ti-Al+prGO were loaded individually into graphite dies (2-cm diameter) lined with graphite foils and covered by graphite blankets, and were SPS-ed in dynamic vacuum. The SPS conditions were those already used successfully in B₄C ceramics with Ti-Al [40]: target temperature of 1900 °C (as measured using an axial optical pyrometer), heating ramp of 100 °C/min, soaking time of 30 min, and pressure of 75 MPa (applied at 300 °C). The resulting B₄C composites were characterized microstructurally by scanning electron microscopy (SEM; Quanta 3D, FEI, The Netherlands) at the fracture surfaces, and Raman spectroscopy at polished, top surfaces. They were also characterized mechanically by Vickers indentation (MV-1, Matsuzawa, Japan) at 9.8 N load. Two types of tests were done, ones on the polished, top surface to evaluate the hardness (10 indents per sample) [21] and others on the gold-coated, polished cross-section surface to elucidate how the Vickers cracks interacted with the microstructures. The observations of the residual Vickers indents were performed in all cases by optical microscopy (OM; Epiphot 300, Nikon, Japan). The Vickers indents were also selectively observed by SEM (S-3600N, Hitachi, Japan).

3. Results and discussion

The environmentally friendly fabrication of the orthotropic and isotropic superhard B₄C/rGO composites developed here comprises the steps of aqueous colloidal processing and SPS described next.

3.1. Aqueous colloidal processing of B₄C+Ti-Al+GO/prGO powder mixtures

Fig. 1 shows the dependence of the zeta potential on pH for the individual dilute aqueous suspension of GO without and with different PEI additions. It is clear that GO is negatively

1
2
3
4 charged over the entire range of pHs investigated, either with no isoelectric point or with one at a
5
6 very acidic pH ($\text{pH} < 2$). It is also seen that the zeta potential increases relatively little in
7
8 magnitude with pH, and is (in absolute value) always greater than 30 mV. In principle, GO
9
10 would then be colloidally stable in water at practically any pH. This is because this GO is
11
12 inherently functionalized with hydroxyl, carbonyl, epoxy, and alkoxy surface groups with a C:O
13
14 ratio of 2.4-2.6, and so is hydrophilic and easily dispersible in water. Nonetheless, unfortunately
15
16 it is not possible to prepare well-dispersed aqueous suspensions of $\text{B}_4\text{C} + \text{Ti-Al} + \text{GO}$ at neutral pH
17
18 because B_4C and Ti-Al are not colloidally stable (due to their low zeta potentials) [40]. Indeed, it
19
20 has recently been demonstrated that the aqueous concentrated suspensions of $\text{B}_4\text{C} + \text{Ti-Al}$ are well
21
22 dispersed at neutral pH if deflocculated with a cationic polyelectrolyte [40], conditions at which
23
24 the B_4C and Ti-Al particles are charged positively with zeta potentials of ~ 50 mV (see Fig. 1).
25
26 Introducing GO into these suspensions would then result in the undesirable hetero-aggregation,
27
28 not in the sought-for co-dispersion, of the negatively-charged GO nanoplatelets with the
29
30 positively-charged B_4C and Ti-Al particles.
31
32
33
34
35
36
37

38 Logically, it is possible to change the charge of GO from negative to positive by cationic
39
40 polyelectrolytes, and in particular by PEI which would thus simplify the route of colloidal
41
42 processing (because PEI is the deflocculant used for B_4C and Ti-Al [40]). Accordingly, Fig. 1
43
44 also shows the evolution of the zeta potential as a function of pH for the individual dilute
45
46 suspension of GO with different PEI additions. Clearly, only 1 wt.% PEI already induces the
47
48 appearance of an isoelectric point for GO at $\text{pH} \sim 4.2$, but it is insufficient for preparing well-
49
50 dispersed suspensions of $\text{B}_4\text{C} + \text{Ti-Al} + \text{GO}$ at neutral pH because at this pH GO still has a negative
51
52 zeta potential (-45 mV), not positive as do B_4C and Ti-Al [40]. With increasing PEI content, the
53
54 isoelectric point of GO gradually shifts to greater pH ($\text{pH} \sim 6.5, 7.0, 7.2, 8.0, 9.3, \text{ and } 9.7$ for PEI
55
56
57
58
59
60
61
62
63
64
65

1
2
3
4 contents of 2, 3, 4, 6, 8, and 10 wt.%, respectively) while the zeta potential below the isoelectric
5
6 point increases markedly, which is clear evidence for electrosteric stabilization. More
7
8 importantly, it is seen that ~8 wt.% PEI already provides GO with the required (positive) zeta
9
10 potential of ~50 mV exhibited by B₄C [40] and Ti-Al [40] with 1 wt.% PEI at neutral pH.
11
12
13

14 Fig. 2 shows the dependence of the zeta potential on pH for the individual dilute aqueous
15
16 suspension of prGO without and with different PEI additions. It is seen that, unlike GO, prGO
17
18 exhibits an isoelectric point at pH~2.6. This is because this prGO was prepared by the thermal
19
20 reduction of GO at 400 °C, which resulted in the partial removal of oxygen-containing functional
21
22 groups (prGO thus has less hydroxyl, carbonyl, and epoxy groups than GO, as well as a much
23
24 higher C:O ratio of 7-8). Nonetheless, neither can prGO be used directly for preparing well-
25
26 dispersed suspensions of B₄C+Ti-Al+prGO at neutral pH because, like GO, at this pH its zeta
27
28 potential is still negative (-40 mV) [40]. Consequently, adding PEI is also necessary in this case.
29
30 This is especially the case given the very hydrophobic nature of prGO, and its consequent low
31
32 dispersibility in water. As expected, PEI addition gradually shifts the isoelectric point of prGO to
33
34 greater pH (pH~4.6, 6.0, 9.3, and 10.0 for PEI contents of 1, 2, 4, and 6 wt.%, respectively).
35
36 Indeed, prGO and GO have similar isoelectric points for low PEI contents (i.e., 1 and 2 wt.%),
37
38 above which prGO has much higher isoelectric points. Interestingly, ~6 wt.% PEI already
39
40 provides prGO with the required (positive) zeta potential of ~50 at neutral pH, which is ~2 wt.%
41
42 PEI less than for GO.
43
44
45
46
47
48
49

50 Well-dispersed concentrated suspensions of B₄C+Ti-Al+GO and B₄C+Ti-Al+prGO will
51
52 then be prepared at neutral pH (pH~6.9-7.0) by adding 8 wt.% PEI for GO, 6 wt.% PEI for
53
54 prGO, and 2 wt.% PEI for both B₄C and Ti-Al [40]. The composition of solids of these
55
56 suspensions can only be formulated knowing the mass loss that both GO and prGO will undergo
57
58
59
60
61
62
63
64
65

1
2
3
4 during SPS. Consequently, pellets of GO and prGO were compacted individually, weighed, and
5
6 heated with the SPS furnace up to 1900 °C in vacuum, and re-weighed, determining that their
7
8 mass losses were ~54.4 and 42.5%, respectively. As expected, GO lost more weight (~12%) than
9
10 prGO, attributable to its greater abundance of oxygen-containing functional groups.
11
12 Consequently, to obtain the desired B₄C composites with 4.9 vol.% Ti-Al and 2 vol.% rGO one
13
14 needs to prepare concentrated suspensions with compositions in wt.% of 89.07B₄C+7.02Ti-
15
16 Al+3.91GO and of 89.82B₄C+7.08Ti-Al+3.10prGO.
17
18
19
20

21 Unfortunately, the attempts to prepare these suspensions to total solids loadings of 30 and
22
23 25 vol.% were unsuccessful because, as shown in Figs. 3A-B, during the gradual addition of
24
25 GO/prGO the suspensions coagulated as grainy solids. In this scenario, aqueous colloidal
26
27 processing is unfeasible. Fortunately, however, the situation changed when the total solids
28
29 loading was reduced to 20 vol.%, in which case it was possible to prepare the desirable flowable
30
31 suspensions, as shown in Fig. 3C.
32
33
34
35

36 The concentrated suspensions (20 vol.% of total solids) of 89.07B₄C+7.02Ti-Al+3.91GO
37
38 and 89.82B₄C+7.08Ti-Al+3.10prGO were then characterized rheologically before and after
39
40 sonication for various times. The objective was to identify the optimal co-dispersion conditions
41
42 of B₄C and Ti-Al with GO/prGO platelets as coarse/fine as possible (for fabricating the
43
44 orthotropic/isotropic composites). Fig. 4 shows the flow curve of the concentrated suspension of
45
46 B₄C+Ti-Al+GO prepared only by mechanical agitation. This suspension exhibits a shear-
47
48 thinning rheological behaviour (i.e., pseudo-plastic behaviour without yield point) with some
49
50 thixotropy, indicative of good dispersion. The visual observations shown in Fig. 4 confirmed that
51
52 it is indeed very flowable. This suspension has then the sought-for good dispersion of the B₄C,
53
54 Ti-Al, and GO, while preserving the coarse nature of the starting flaky GO platelets.
55
56
57
58
59
60
61
62
63
64
65

1
2
3
4 Consequently, this suspension was freeze-dried, thus obtaining the starting powder mixture from
5
6 which orthotropic B₄C/rGO composites would be fabricated. Note that in this case sonication is
7
8 detrimental because it will re-exfoliate and re-fragment the desired flaky coarse GO platelets.
9
10 Certainly, the flow curves shown in Fig. 4 for the concentrated suspensions of B₄C+Ti-Al+GO
11
12 sonicated for 1 and 2 min confirm that this is what occurs. It is seen that the sonicated
13
14 suspensions exhibit a very shear-thinning rheological behaviour (i.e., plastic behaviour with yield
15
16 point), with an increasing yield stress. The direct visual observations shown in Fig. 4 confirmed
17
18 that they are thicker and indeed resemble pastes. What happens is that sonication results in a
19
20 greater number of thinner and smaller, but still relatively coarse, GO platelets, which, at rest
21
22 conditions, are randomly oriented within the suspension between the B₄C and Ti-Al particles.
23
24 Owing to their high aspect ratio, larger number, and random orientation, these newly-formed GO
25
26 platelets offer a great overall resistance to the flow for low shear rates to such an extent that the
27
28 suspension has a yield stress. However, shearing above the yield stress orients the GO platelets
29
30 in parallel to the flow direction, thus reducing the suspension's viscosity.
31
32
33
34
35
36
37

38 Fig. 5 shows the flow curves of the concentrated suspension of B₄C+Ti-Al+prGO as a
39
40 function of the sonication time. Unlike before, sonicating is now key to obtaining prGO platelets
41
42 as fine as possible for fabricating the isotropic B₄C/rGO composites. It is seen that the sonicated
43
44 suspensions exhibit the desired shear-thinning rheological behaviour with little thixotropy,
45
46 whereas the non-sonicated suspension is more viscous and thixotropic. The direct visual
47
48 observations shown in Fig. 5 confirmed that they are all fluid, although in this case sonication is
49
50 indeed beneficial for the dispersion because the flow response got better. Most likely, this is
51
52 because (i) the starting prGO platelets are much finer and smaller than the GO platelets, and
53
54 become even much finer and smaller after sonication, and (ii) the concentrated suspensions
55
56
57
58
59
60
61
62
63
64
65

1
2
3
4 contain less prGO than GO because prGO loses less mass than GO during SPS. The optimal
5
6 sonication time is 2 min, above which dispersion got worse (because the viscosity increases).
7
8 This last is because the excess of sonication causes some re-agglomeration once the heat-induced
9
10 surface activation starts to predominate over dispersion [41]. Consequently, the suspension
11
12 sonicated for 2 min was freeze-dried thus obtaining the starting powder mixture from which
13
14 isotropic B₄C/rGO composites would be fabricated.
15
16
17
18
19
20

21 **3.2. Spark plasma sintering of orthotropic and isotropic B₄C/rGO composites**

22
23 Figs. 6 and 7 present SEM images at different magnifications of the fracture surface of
24
25 the B₄C composites fabricated by SPS from the optimized powder mixtures of B₄C+Ti-Al+GO
26
27 and B₄C+Ti-Al+prGO, respectively. It is seen that the two composites are, thanks to the Ti-Al
28
29 additives, well densified. Fig. 8 compares the Raman spectra of the composites and their powder
30
31 mixtures, indicating that the former contains rGO nanoplatelets, not the parent GO/prGO
32
33 nanoplatelets. This is because the intensity ratio of the D to G bands is lower in the composites,
34
35 which is indicative of thermal reduction of GO/prGO to rGO *in situ* during SPS. The B₄C/rGO
36
37 composites, however, exhibit notable microstructural differences regarding their distribution of
38
39 nanoplatelets. Thus, the B₄C/rGO composite fabricated from B₄C+Ti-Al+GO is orthotropic
40
41 because its rGO platelets are preferentially aligned in planes perpendicular to the pressing
42
43 direction during SPS (Figs. 6A-B). Also, these rGO platelets are coarse and span longitudinally
44
45 tens of microns because they are actually flaky aggregates of thick, large rGO nanoplatelets (Fig.
46
47 6C). On the contrary, it is hard to distinguish rGO platelets in the B₄C/rGO composite fabricated
48
49 from B₄C+Ti-Al+prGO (Figs. 7A-B). Its microstructure is fairly isotropic because most of its
50
51

5
6 (Fig. 7C).
7

8
9 Interestingly, the two B₄C/rGO composites are equally superhard, with a Vickers
10 hardness of ~31-32 GPa. They are therefore only slightly softer than the reference material
11 without rGO, whose Vickers hardness is 34±1 GPa [40]. This is simply because rGO is relatively
12 soft. However, as seen in the OM and SEM observations of Figs. 9 and 10, they exhibit marked
13 differences in how the Vickers cracks propagated through their microstructures. Thus, in the
14 orthotropic B₄C/rGO composite, the cracks run very little in parallel to the pressing direction
15 during SPS because the flaky rGO platelets arrest their propagation (marked toughening), and
16 much more in the perpendicular direction (virtually no toughening) (Figs. 9A and B). The
17 anisotropic toughening power of the coarse rGO platelets is more evident in Figs. 9C and D,
18 which show that no cracks are able to emanate from the corner of the plastic impression when
19 this falls where there are coarse rGO platelets. In the isotropic B₄C/rGO composite, however, the
20 Vickers cracks run equally in both directions (Fig. 10A), but they propagated tortuously (Fig.
21 10B), indicating active interaction with the thin rGO platelets and therefore moderate
22 toughening. Indeed, recent detailed toughness measurements on Al₂O₃/rGO composites
23 demonstrate that (i) those with orthotropic microstructure are markedly tough with a rising *R*-
24 curve in the direction perpendicular to the rGO platelets, but are practically untoughened in the
25 direction parallel to the rGO platelets [28], and that (ii) those with isotropic microstructure are
26 moderately toughened in any direction with a shallower *R*-curve [28]. According to the Vickers
27 indentation tests, this is the present case, and therefore future work (beyond the scope of this
28 processing study) is needed to measure these *R*-curves.

1
2
3
4 Anisotropy in functional properties is also expected for the present orthotropic B₄C/rGO
5
6 composites. Certainly, earlier study on orthotropic composites of B₄C reinforced with graphene
7
8 platelets (GPLs) has demonstrated greater electrical conductivity in the direction parallel to the
9
10 GPLs [33]. This is also true for orthotropic SiC/GPL composites [42], for which the thermal
11
12 diffusivity has also been found to be greater in the direction parallel to the GPLs [43,44]. Higher
13
14 electrical and/or thermal conductivities in parallel to the reinforcements have also been reported
15
16 for Al₂O₃/GPL nanocomposites [45], and for AlN/GPL [46], 8YSZ/GPL [47], and 3YTZP/GPL
17
18 composites [48], to name but a few examples.
19
20
21
22

23
24 What is remarkable is that the feasibility has been demonstrated of fabricating
25
26 controllably by the same processing route B₄C/rGO composites with different microstructural
27
28 designs, for their use on demand depending on the complexity of the mechanical loads and
29
30 particular needs in each given engineering application. Also, this processing route is simple, and
31
32 easily adaptable/extensible to make other orthotropic and isotropic ceramic/rGO composites
33
34 (with the desired ceramic matrix, tailored content of sintering additives (if any), and required
35
36 percentage of GO nanoplatelets), provided that all starting powders can be co-dispersible as
37
38 concentrated suspensions (with shear-thinning rheological behaviour) conveniently deflocculated
39
40 (using ideally a common deflocculant, or else a combination of various deflocculants of the same
41
42 charge), in aqueous or non-aqueous media.
43

45
46
47
48
49
50

51 **4. Conclusions**

52
53 The processability of fully-dense B₄C/rGO composites with orthotropic and isotropic
54
55 microstructural designs on demand has been studied. Based on the results and analyses, the
56
57 following conclusions can be drawn:
58
59
60
61
62
63
64
65

- 1
2
3
4 1. A simple processing route combining aqueous colloidal processing with transient liquid-
5
6 phase assisted SPS has been developed that is customizable to obtain both orthotropic
7
8 and isotropic B₄C/rGO composites, controllably.
9
- 10
11 2. In this route, the orthotropic B₄C/rGO composites are obtained by using a source of
12
13 coarse rGO platelets and imposing smooth co-dispersion conditions during aqueous
14
15 colloidal processing to avoid their re-exfoliation/re-fragmentation.
16
17
- 18
19 3. Contrarily, the isotropic B₄C/rGO composites are obtained by using a source of fine rGO
20
21 platelets and imposing intensive co-dispersion conditions to ensure their re-exfoliation/re-
22
23 fragmentation.
24
- 25
26 4. Both types of B₄C/rGO composites are equally superhard (~31-32 GPa). Nonetheless, the
27
28 orthotropic composites exhibit marked toughening and virtually no toughening for cracks
29
30 propagating perpendicularly and in parallel to the rGO reinforcements, respectively. The
31
32 isotropic composites exhibit however moderate toughening for any crack.
33

Table and Table Caption

Table 1. Features of the starting powders. Purity, morphology, and size are as provided by the manufacturer's specifications. Densities were measured experimentally by He-pycnometry.

Powder	Purity (%)	Density (g/cm ³)	Morphology	Size (μm)
B ₄ C	>99	2.559	particulate	~0.7
Ti-Al	>99.8	3.841	particulate	~38
GO	>99	1.845	nanoplatelets	~10 diameter, 0.005 thickness
rGO	>99	2.372	nanoplatelets	~5 diameter, 0.002 thickness

Figure Captions

Figure 1. Dependence of the zeta potential on pH and PEI deflocculant content for the individual dilute suspensions of GO, as indicated. Dots are the experimental data, and the lines are guides for the eye. The grey stripe denotes the zone excluded for low colloidal stability. The blue stripe denotes the zones excluded for restrictions of charge sign or pH. The curves of zeta potential for B₄C and Ti-Al with 1 wt.% PEI are also included as references for the co-dispersion [40].

Figure 2. Dependence of the zeta potential on pH and PEI deflocculant content for the individual dilute suspensions of prGO, as indicated. Dots are the experimental data, and the lines are guides for the eye. The grey stripe denotes the zone excluded for low colloidal stability. The blue stripe denotes the zones excluded for restrictions of charge sign or pH. The curves of zeta potential for B₄C and Ti-Al with 1 wt.% PEI are also included as references for the co-dispersion [40].

Figure 3. Optical photographs showing the visual appearance directly observable just after dispersing the entire amount of prGO into the water for total solids loadings of (A) 30, (B) 25, and (C) 20 vol.%.

Figure 4. Flow curves as a function of sonication time for the 89.07B₄C+7.02Ti-Al+3.91GO concentrated suspension prepared to 20 vol.% total solids, and optical photographs showing its visual appearance. Sonication was not prolonged further once the flow curve worsened. The number at the right of each curve denotes the sonication time. The arrows indicate the uploading and downloading stretches of the flow curves.

Table and Table Caption

Table 1. Features of the starting powders. Purity, morphology, and size are as provided by the manufacturer's specifications. Densities were measured experimentally by He-pycnometry.

- A fabrication route based on aqueous colloidal processing plus transient liquid-phase assisted spark-plasma-sintering (SPS) with Ti-Al additives is described for the environmentally friendly obtention of superhard B_4C composites reinforced with reduced graphene oxide (rGO) having orthotropic and isotropic microstructures.
- Orthotropic B_4C /rGO composites, which have coarse rGO platelets preferentially aligned perpendicular to the SPS pressing direction, are prepared from mixtures of B_4C and Ti-Al particles with a source of thick, large rGO nanoplatelets by imposing smooth co-dispersion conditions to avoid platelet re-exfoliation and fragmentation.
- Isotropic B_4C /rGO composites, which have fine rGO platelets randomly oriented, are fabricated from mixtures of B_4C and Ti-Al particles with a source of thin, small rGO nanoplatelets by applying intensive sonication to promote platelet re-exfoliation and fragmentation during co-dispersion.
- The orthotropic and isotropic B_4C /rGO composites are equally superhard, but their microstructures interact differently with the cracks.
